Application: Safety Engineer, Loitering Systems

Dear STARK team,

For the last five years I have built safety for a system, no regulation covered. Vay operates around 200 remotely driven vehicles on public roads in Las Vegas with no one inside. When I joined there was no teledriving regulation, so we derived the safety framework from first principles, built the safety function and its processes from scratch, and took it through an independent TÜV SÜD assessment to Europe's first approval to operate without a safety driver. That is roughly the situation your Safety Engineer walks into: a new class of unmanned system, hard safety questions, and a program to establish rather than inherit.

My standards background is automotive: ISO 26262 across the full lifecycle, SOTIF, safety cases to UL 4600. I have not worked on MIL-STD-882E or AOP-52, and I won't pretend otherwise. But the machinery underneath is the same: hazard analysis, risk assessment and acceptance, safety requirements with a verifiable path to closure, safety assessment of software that controls a physical system. The analyses 882E asks for (PHA, SSHA, SHA) are the ones I run under automotive names, and I have made this kind of translation before, moving from OEM ADAS work into an unregulated domain and producing documentation a certification body accepted.

Two practical points. As a German citizen I expect no issues obtaining and maintaining the required security clearance (ZÜP). My German is certified B1 and in daily use somewhat above that.

I would like to help build the safety program at STARK while its shape is still being decided, and I am open to relocating to Munich for it.

Best regards,

Sourabh Porwal
